

# Semantic Analysis

---

TEACHING ASSISTANT: DAVID TRABISH

# Semantic Analysis

Perform various checks:

- Type checking
  - $1 + \text{"1"}$
- Scopes
  - Undefined variables
- Other
  - Division by zero
  - Visibility semantics in classes (public, private, ...)

# Visitor Design Pattern

Perform computations over tree-like data structures

*visit(node):*

*// do something with node*

$r_1 = \text{visit}(\text{node.child}_1)$

$r_2 = \text{visit}(\text{node.child}_2)$

...

*// do something with  $r_1, r_2, \dots$*

# Visitor Design Pattern: Example

Printing the AST

```
visit(node):  
    print(node)  
    for child in node.children:  
        visit(child)
```

# Symbol Table

- Stack of scopes
- Each scope contains information about identifiers
  - Name
  - Type (int, string, ...)
  - Kind (variable, function, method, ...)

# Symbol Table

# Symbol Table Operations

- **Insert** symbol
- **Lookup** symbol
- **Enter** scope
- **Exit** scope

# Symbol Table: Insert

Example:

- Insert(z, int, variable)

main scope

ID	Type	Kind
x	int	variable
y	int	variable

*scope<sub>1</sub>*

ID	Type	Kind
tmp	int	variable

*scope<sub>2</sub>*

# Symbol Table: Insert

Example:

- Insert(z, int, variable)

main scope

ID	Type	Kind
x	int	variable
y	int	variable

*scope<sub>1</sub>*

ID	Type	Kind
tmp	int	variable
z	int	variable

*scope<sub>2</sub>*

# Symbol Table: Lookup

Example:

- Lookup(y)
  - Start from the top of the stack, return **first** match

main scope

# Symbol Table: Lookup

Example:

- Lookup(y)
  - Start from the top of the stack, return **first** match

main scope

# Symbol Table: Enter

main scope

ID	Type	Kind
x	int	variable
y	int	variable

$scope_1$

ID	Type	Kind
tmp	int	variable

$scope_2$

# Symbol Table: Enter

main scope

ID	Type	Kind
x	int	variable
y	int	variable

$scope_1$

ID	Type	Kind
tmp	int	variable

$scope_2$

ID	Type	Kind

$scope_3$

# Symbol Table: Exit

main scope

ID	Type	Kind
x	int	variable
y	int	variable

$scope_1$

ID	Type	Kind
tmp	int	variable

$scope_2$

# Symbol Table: Exit

main scope

ID	Type	Kind
x	int	variable
y	int	variable

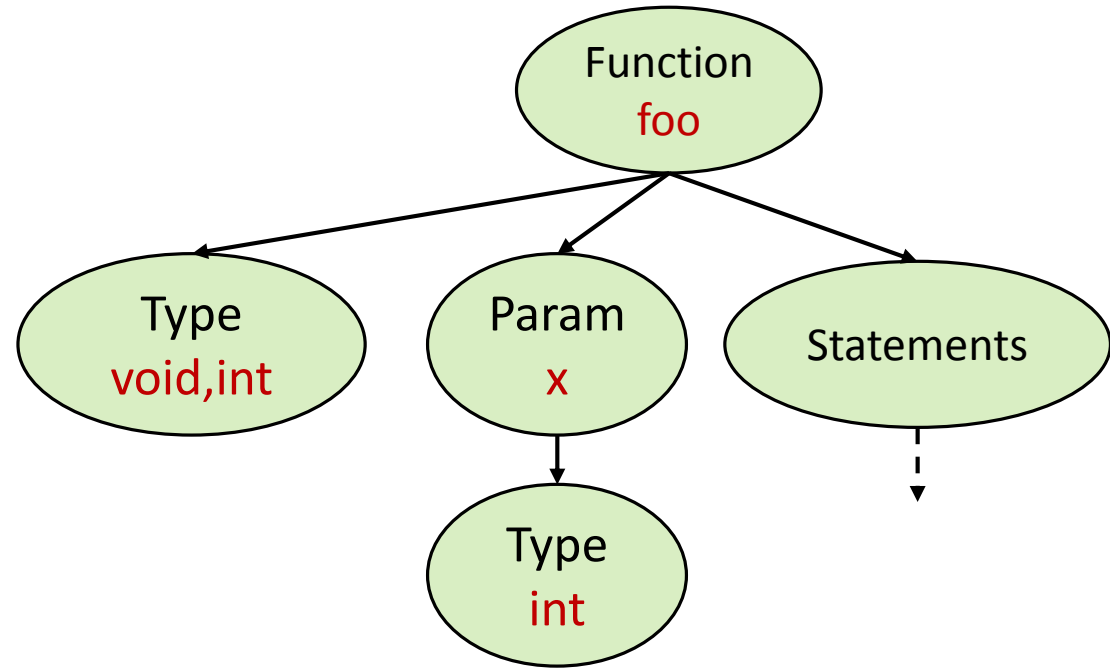

*scope<sub>1</sub>*

# Symbol Table Construction

- Identifier declaration
  - Insert
- Identifier reference
  - Lookup
- When visiting a new block
  - Enter
- When leaving a block
  - Exit

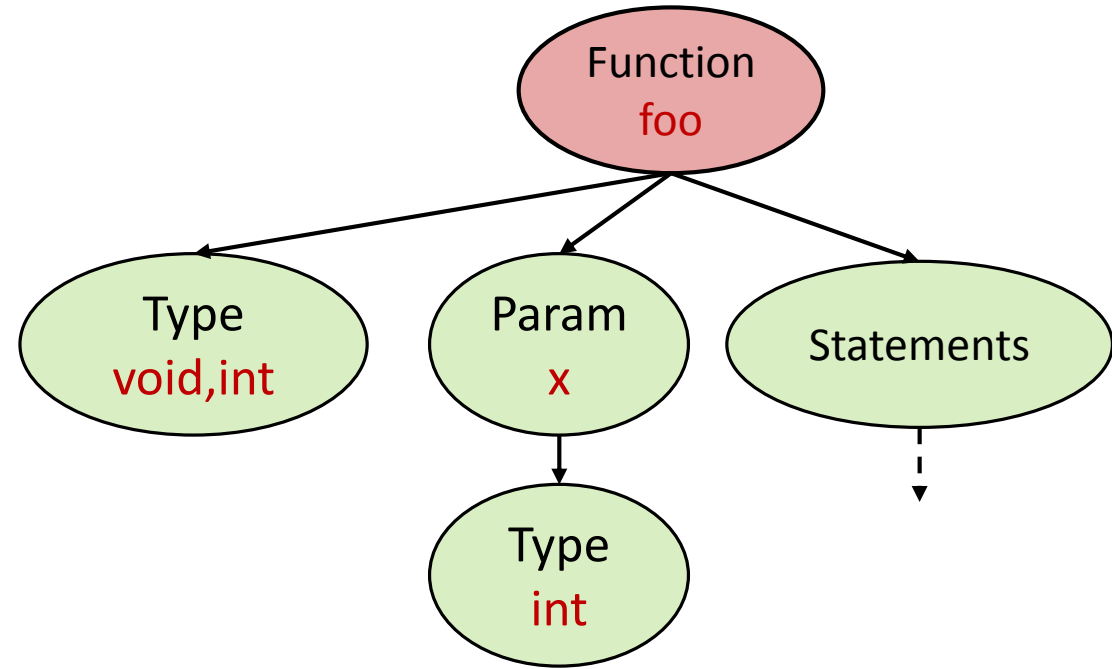

```
void foo(int x) {  
    int a = 1;  
    int b = 2;  
    if (x) {  
        string a = "abc";  
    }  
}
```

```
void foo(int x) {  
    int a = 1;

    }  
}
```

ID	Type	Kind
foo	void,int	function

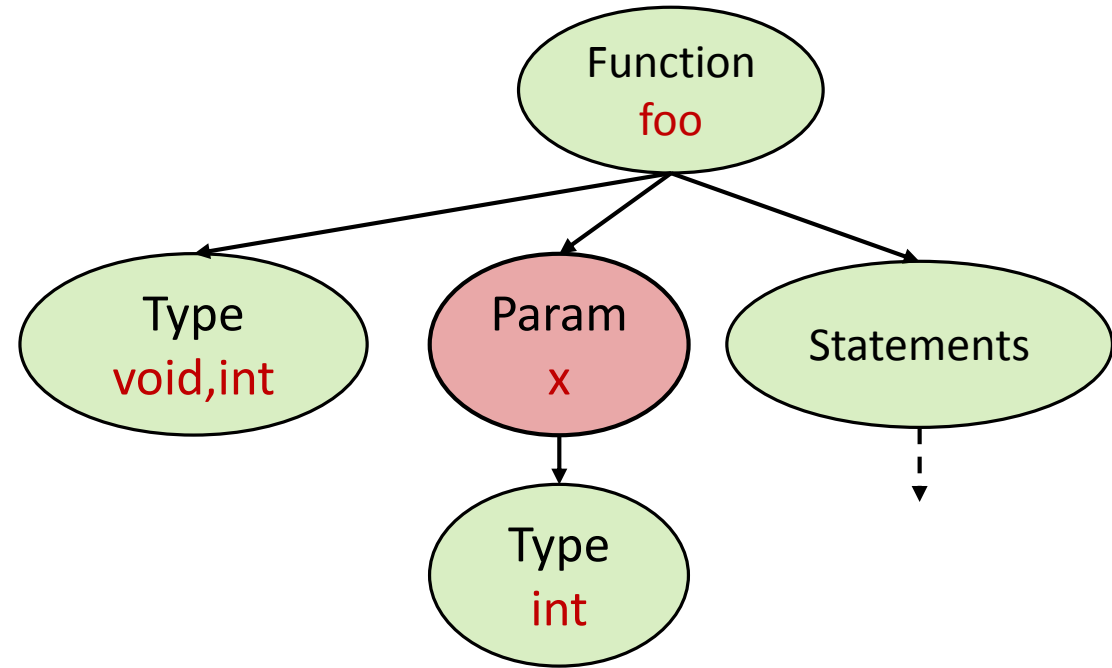

```
void foo(int x) {  
    int a = 1;  
    int b = 2;  
    if (x) {  
        string a = "abc";  
    }  
}
```

# Type Checking

Goals:

- Type correctness of expressions
- Compute type of expressions

Performed using:

- AST visitor
- Symbol table

# Type Checking

Basic algorithm:

*visit(node):*

$t_1 = \text{visit}(\text{node.child}_1)$

...

$t_n = \text{visit}(\text{node.child}_n)$

$\text{return } \underbrace{\text{compute\_type}(t_1, \dots, t_n)}$

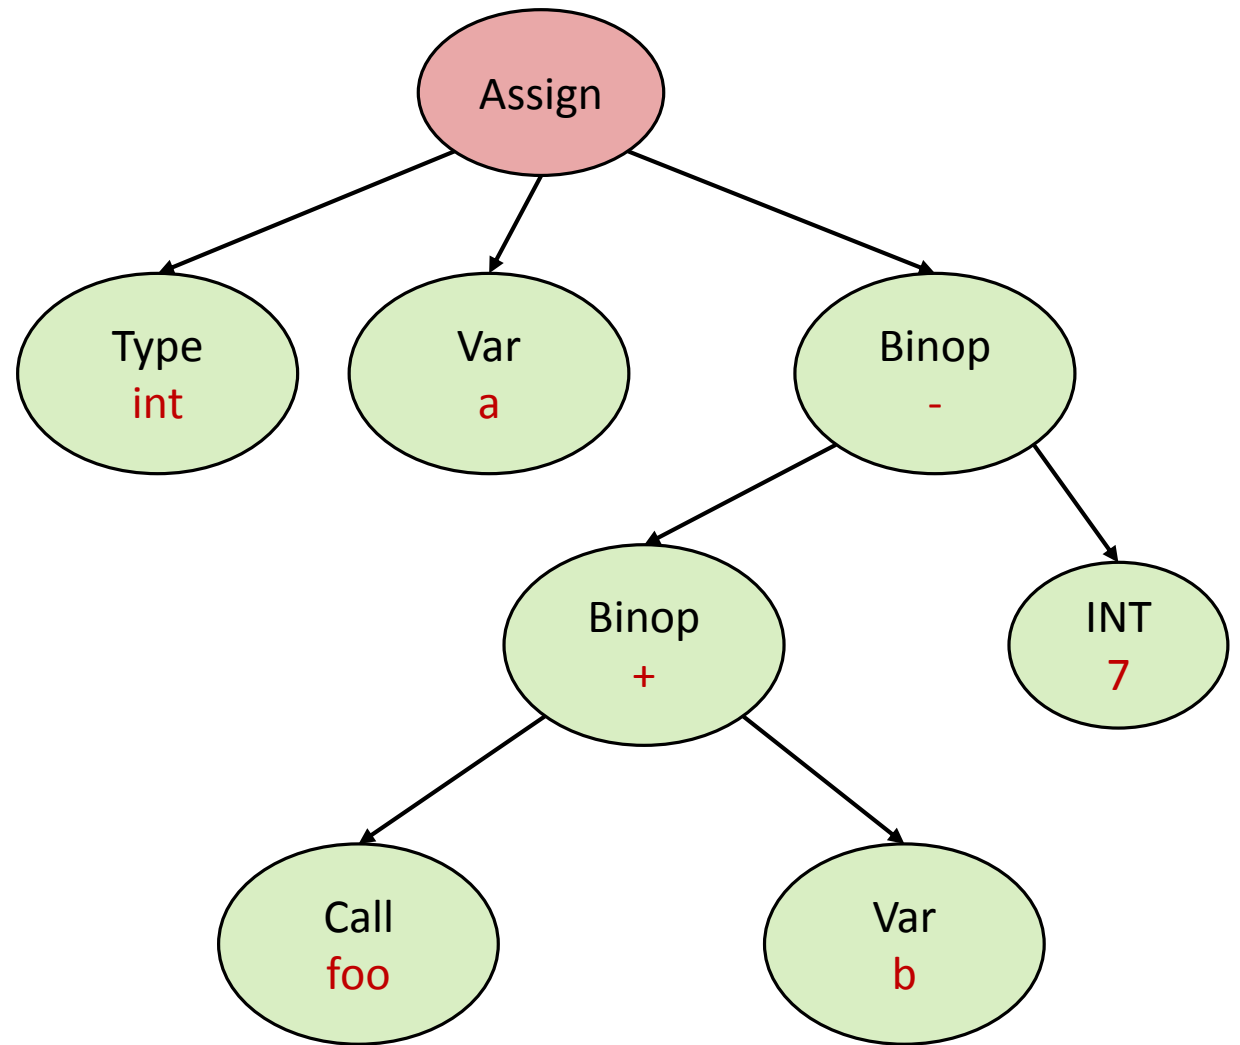

node specific

```
int a = foo() + b - 7;  
...
```

ID	Type	Kind
foo	int,void	function

ID	Type	Kind
b	int	variable

```
int a = foo() + b - 7;  
...
```

ID	Type	Kind

# Implementation

The AST is traversed in a top-down manner:

- Each AST node class, has a **visit** API
  - Performs the relevant semantic checks
  - May call the visitors of the node's children
- The traversal starts from the root node

# Implementation

```
class ASTExpBinOp {
    public ASTExp left;
    public ASTExp right;
    ...
    public Type visit() {
        Type t1 = left.visit();
        Type t2 = right.visit();
        if (t1 != t2) { // error }
        // check if op is supported w.r.t. t1/t2
        return t1;
    }
}
```

# Implementation

```
class ASTStatmentList {  
    public ASTStatement head;  
    public ASTStatmentList tail;  
    ...  
    public Type visit() {  
        if (head)  
            head.visit();  
        if (tail)  
            tail.visit();  
        return null;  
    }  
}
```

# Exam Question

We extend the language with automatic type inference:

- Can use **auto** when the declaration has an initial value

Describe the changes required in:

- Lexical analysis
- Syntactic analysis
- Semantic analysis

```
auto i := 8 + 100;  
auto s := "1234";  
class A {}  
A a := new A;  
auto b := a;
```

# AST Annotations

---

# AST Annotations

Annotate the AST with information needed for **code generation**:

- Variable offsets
- Parameter offsets
- Class layouts
- Type sizes

# Runtime Memory Layout

# Stack

# MIPS: Instructions Set

MIPS has 32 registers:

- t0, ..., t9 (general purpose)
- a0, a1, a2, a3 (arguments)
- v0 (return value)
- sp (stack pointer)
- fp (frame pointer)
- ra (return address)
- ...

# MIPS: Instructions Set

Setting registers values:

- li
- move

```
li $t0, 3  
move $t1, $t2
```

# MIPS: Instructions Set

Arithmetic instructions operate on registers and constants:

- add, sub, ...

```
add $t2, $t0, $t1  
sub $t3, $t1, 7
```

# MIPS: Instructions Set

Read from memory:

- lw

```
lw $t0, 0($t1)
```

```
lw $t0, 12($t1)
```

```
lw $t0, -8($t1)
```

# MIPS: Instructions Set

Write to memory:

- `sw`

```
sw $t0,0($t1)
```

```
sw $t0,12($t1)
```

```
sw $t0,-8($t1)
```

# Stack

```
int f(int x, int y) {  
    int z = x + y;  
    return z;  
}  
int g() {  
    int x = f(10, 20)  
}
```

}
```

# Storing Values

In our language, values can be stored in 32-bit registers:

- type **int** (4 bytes)
- type **string** (4 bytes pointer)
- arrays (4 bytes pointer)
- classes (4 bytes pointer)

# Field Offsets

How does an object of this class look in memory?

```
class Point {  
    int x;  
    int y;  
}  
void f(Point p) {  
    p.x = 0xaa;  
    p.y = 0xbb;  
}
```

# Field Offsets

How does an object of this class look in memory?

```
class Point {  
    int x;  
    int y;  
}  
void f(Point p) {  
    p.x = 0xaa;  
    p.y = 0xbb;  
}
```

# Field Offsets

How does an object of this class look in memory?

```
class Point {  
    int x;  
    int y;  
}  
  
void f(Point p) {  
    p.x = 0xaa;  
    p.y = 0xbb;  
}
```
